Important Note: Submit all your codes to SUCourse as a single zip file. Deadline for submission to SUCourse is **15:30**.

Things to do:

• In this lab we will recover the pose of a camera from two images taken from different viewpoints by estimating the Essential Matrix (E) using 8-point algorithm. To do that we will make use of epipolar geometry. First run "lab8.m" file to generate 3D world points and obtain their corresponding image points from two different views (Figure 1).

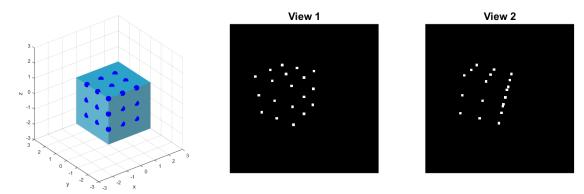

Figure 1: 3D world points and their corresponding image points from two different views

- Note that the matrix K which includes intrinsic camera parameters is already known (calibrated two-view problem). Thus, start your implementation by transforming points in pixel coordinates in both views by multiplying them with the inverse of K matrix.
- Initially, select 8 point pairs properly to avoid degenerate configuration for estimating a reliable Essential Matrix. For each point pair, obtain the vector a appropriately and stack 8 of them in the rows of the X matrix as follows:

$$a = \begin{bmatrix} x_1 x_2 & x_1 y_2 & x_1 z_2 & y_1 x_2 & y_1 y_2 & y_1 z_2 & z_1 x_2 & z_1 y_2 & z_1 z_2 \end{bmatrix}^T$$
 (1)

$$X = [a_1^T; \ a_2^T; \ \dots \ a_8^T] \tag{2}$$

• Since $XE^s = 0$, where E^s is the stacked version of the Essential Matrix, the eigenvector associated with the smallest eigenvalue of X^TX gives the solution in stacked form. Now, obtain the Essential Matrix E and cure it to satisfy Essential Matrix Characterization theorem, and obtain the normalized essential matrix.

Hint: Replace the singular values of the estimated E with $\sigma_1 = \sigma_2 = 1, \sigma_3 = 0$ and verify that $U, V \in SO(3)$ for $E = U \Sigma V^T$.

• Next, find the epipoles (e_1, e_2) and the coefficients of epipolar lines for a selected point pair. Then, verify that the image point and the epipole for one view are on the epipolar line.

Hint: To find epipoles, you can use null (E) function, which gives the nullspace from the right.

• Finally, recover the rotation and the translation of the camera. Possible poses are recovered as follows:

$$(\hat{T}_1, R_1) = (UR_z(+\frac{\pi}{2})\Sigma U^T, UR_z^T(+\frac{\pi}{2})V^T) \qquad (\hat{T}_2, R_2) = (UR_z(-\frac{\pi}{2})\Sigma U^T, UR_z^T(-\frac{\pi}{2})V^T) \qquad (3)$$

Your results should look like as follows:

True E =			Estimated $E =$			
0	-1.0000	0	0.0025	-0.3198	0.0025	
-0.3615	0	-3.1415	-0.1249	0.0035	-0.9922	
0	3.0000	0	-0.0059	0.9475	0.0054	
True Rc2cl =		Estimated Rc2cl =				
0.9063	0	-0.4226	0.9001	0.0037	-0.4356	
0	1.0000	0	-0.0023	1.0000	0.0038	
0.4226	0	0.9063	0.4356	-0.0024	0.9001	
True Tc2cl	=	Estimated Tc2cl =				
3		0.9475				
0		0.0041				
1		0.3198				

Note that rotation estimate is very close to the true rotation, while transition estimate is recovered up to a scale.

Post Lab

- Select 8 points on the same plane and recover the pose of the camera by estimating the essential matrix. Repeat the same procedure for each plane.
- Now select all the points and recover the pose of the camera by estimating the essential matrix.

Provide the images of two views for each case and compare the results. Explain the steps of the followed procedure. Discuss your findings and comment on which recovered pose would you pick.

Deadline for post lab report submission to SUCourse: 19 December 2022, 23:55.
